The Navy's Radio Teletype Systems Afloat

In the history of naval progress, communications play an increasingly important role. There was a time when visual devices were the only means of communication between ships and between a ship and the shore.

The semaphore, the flag-hoist, and the flashing light were the primary means of communication, nothing more. When these were the only means of communication for a ship, out of sight meant out of communication. A ship alone on the high seas was isolated from the rest of the world.

Radio Communication

Then came radio communications—first, the telegraph key with the dot-and-dash code that is now known as CW; and later, voice radio communications. Now, a ship at sea can be in communication with other ships and the shore at all times. Being out of sight no longer means out of communication.

Following the discovery of the principles of radio, the use of naval communications increased in volume as rapidly as the number of circuits and the efficiency of equipment permitted. Radio systems soon were overloaded.

To lighten the load of CW and voice radio communications, the Navy needed a new means of dependable, rapid radio communication. The answer to this problem was "radio Teletype." The basic equipment for a shipboard radio Teletype installation is shown in figure 1.

The Navy uses two radio Teletype systems afloat. One, the tone modulated system for short-range operations, is similar to the familiar AM radio. The other, the carrier frequency-shift system for long-range operations, is similar to the standard FM radio. The two systems are shown integrated in figure 1. This article describes the general principles that apply to the operation of radio Teletype equipment.

The teleprinter sends out a continuity of direct current on-and-off pulses (or timed intervals of current and no current, as in figure 2). An "on" or "current" interval is called a "mark" or marking impulse. An "off" or "no-current" interval is a "space" or spacing impulse.

The marks and spaces are generated in various code groups; that is, one group is produced for each character or function being transmitted. A group has five units.

FIGURE 2. Continuity of direct current on-and-off pulses or timed intervals of current and no current.
The gap between the teleprinters must be bridged by radio. To bridge the gap, a radio transmitter and receiver are needed. The radio transmitter produces a radiofrequency carrier wave to carry the mark and space intelligence. Also, a device such as a keyer is needed to change the direct current pulses from the teleprinter into corresponding mark and space modulation for the carrier wave in the transmitter. The radio receiver and a converter are required to change the radiofrequency signal back to direct-current pulses.

The differences in the Navy's two radio Teletype systems, as well as their names, are derived from the direct current mark and space pulses for the teleprinter.
nature of the carrier wave used—the tone modulated carrier wave for short-range work and the carrier frequency shift system for long-range work.

Figure 3 delineates a modulated carrier wave with audio tone impulses impressed on the radiofrequency carrier wave, with corresponding direct-current mark and space signals.

Figure 4 shows a carrier frequency shift wave which increases and decreases to denote mark and space direct-current impulses.

In the operations shown in figures 4 and 5, the direct-current Teletype signal that can travel only by wire becomes, through the medium of a tone terminal or keyer unit, either a tone modulated signal or a carrier frequency shift signal for radio carrier wave transmission.

Short-Range System

To transmit messages by the short-range system, a teleprinter, a tone terminal, and a transmitter are used. The teleprinter sends out a direct-current signal. The signal is changed to audio tones in the tone terminal. The transmitter impresses the audio tones on the carrier and sends out a tone modulated carrier wave (figure 5).

To receive messages with the short-range system, a radio receiver, a tone converter, and a teleprinter are needed. The tone modulated carrier wave enters the receiver which extracts the signal intelligence and sends the audio tones to the tone converter. The converter changes the audio tones into direct-current mark and space pulses for the teleprinter (figure 6).

In practice the same tone terminal is used for the receiving and the sending circuits since it contains both a transmit “keyer” unit and a receiver “converter” unit.

At the transmitting end of the long-range system are a teleprinter, a transmitter, and a frequency shift keyer unit which is built into the newer transmitters. In some older systems the keyer unit is a separate piece of equipment. When the teleprinter is operated, the direct-current teleprinter mark and space signals are changed by the keyer unit into frequency shift intervals. The frequency shift intervals are transmitted as carrier frequency shift signals (figure 7).

On the receiving side of the long-range system, are a receiver, a frequency shift converter, and a teleprinter. When the carrier frequency shift signal enters the receiver, it is detected and changed into a corresponding frequency shifted audio signal. The audio output of the re-
When the direct-current loop is alternately opened and closed by the teleprinter or one of the converters, the result is current and no-current, or mark and space intervals that characterize the direct-current Teletype signal. This is what happens in all of the direct-current loops in both of the Navy’s radio Teletype systems.

The looping current is controlled by a rheostat in the Teletype panel. A common power supply is used for all Teletype panels in shipboard installations. In the front panel of the cabinet each of the six channels, or circuits, has a pair of looping jacks, a set jack, and an additional jack for miscellaneous Teletype requirements.

The numerous terminal and patching connections in the Teletype panel provide many different circuit possibilities. For instance, a keyer or converter circuit that terminates in channel 2 can be patched across to channel 5 to connect with Teletype equipment that ends there. A dummy plug is used to short out the unwanted portion of the circuit.

In both the tone modulated system and the carrier frequency shift system, all Teletype signals pass through the Teletype panel that controls the looping current in all the circuits. The Teletype panel integrates the tone modulated and the carrier frequency shift systems. It provides every possible radio Teletype interconnection available on board ship. This operational flexibility gives maximum efficiency with the fewest circuits and the least amount of equipment in the Navy’s compact radio Teletype systems afloat.
